Lab 2: FIND-S ALGORITHM FOR ENJOY SPORT:

Program 2 – Implement and demonstrate the FIND-S algorithm for finding the most specific hypothesis based on a given set of training data samples. Read the training data from a .CSV file Data set:Enjoysport

a. Enjoysport

Example	Sky	AirTemp	Humidity	Wind	Water	Forecast	EnjoySport
1	Sunny	Warm	Normal	Strong	Warm	Same	Yes
2	Sunny	Warm	High	Strong	Warm	Same	Yes
3	Rainy	Cold	High	Strong	Warm	Change	No
4	Sunny	Warm	High	Strong	Cool	Change	Yes

Algorithm:
initialize h to the most specific hypothesis in H h-(Ø, Ø, Ø, Ø, Ø, Ø)

1. First training example X1=< Sunny, Warm. Normal, Strong Warm Same>. EnjoySport=+ve Observing.The first training example, it is clear that hypothesis h is too specific. None of the "**Ø**" constraints in h are satisfied by this example, so each is replaced by the next more general constraint that fits the example h1 = < Sunny, Warm, Normal, Strong Warm, Same>.

2.Consider the second training example x2 < Sunny, Warm, High, Strong, Warm, Same>. EnjoySport+ve. The second training example forces the algorithm to further generalize h, this time substituting a "?" in place of any attribute value in h that is not satisfied by the new example. Now h2 =< Sunny, Warm, ?, Strong,Warm, Same>

3. Consider the third training example x3< Rainy, Cold, High, Strong, Warm. Change EnjoySport ve. The FIND-S algorithm simply ignores every negative example. So the hypothesis remain as before, so 13=< Sunny, Warm, ?, Strong,Warm, Same>

4. Consider the fourth training example x4 <Sunny, Warm, High. Strong. Cool, Change, EnjoySport +ve. The fourth example leads to a further generalization of h as h4=< Sunny, Warm, ?, Strong, ?, ?>

5. So the final hypothesis is < Sunny, Warm, ?, Strong, ?, ?>

```
import csv
a = []
with open('/kaggle/input/enjoysport/enjoysport.csv', 'r') as csvfile:
    for row in csv.reader(csvfile):
        a.append(row)
    print(a)

print("\n The total no. of training instances are : ", len(a))
num_attribute = len(a[0]) - 1
print("\n The initial hypothesis is : ")
hypothesis = ['0'] * num_attribute
print (hypothesis)
for i in range( 0, len(a)):
    if a[i][num_attribute] == 'yes' :
        for j in range( 0, num_attribute):
            if hypothesis [j] == '0' or hypothesis[j] == a[i][j]
                hypothesis [j] = a[i][j]
            else :
                hypothesis [j] = ~~a[i][j]~~ '?'

    print("\n Hypo for the training instance {} is : \n"
        .format ( i+1), hypothesis)
    ~~print (~~
print ("\n Maximally specific hypothesis for the training instance
    is ")
print (hypothesis)
```

OUTPUT: [['sky', 'airtemp', 'humidity', 'wind', 'water', 'forecast', 'enjoysport'], ['sunny', 'warm', 'normal', strong', 'warm', 'same', 'yes'], ...

The total number of training instances are : 5

The initial hypothesis is :
['0', '0', '0', '0', '0', '0']

The hypothesis for the training instance 1 is :
['0', '0', '0', '0', '0', '0']

The hypothesis for the training instance 2 is :
['sunny', 'warm', 'normal', 'strong', 'warm', 'same']

— " — 3 is :
['sunny', 'warm', '?', 'strong', 'warm', 'same']

— " — 4 is :
['sunny', 'warm', '?', 'strong', 'warm', 'same']

— " — 5 is :
['sunny', 'warm', '?', 'strong', '?', '?']

The maximally specific hypothesis for the training instance is
['sunny', 'warm', '?', 'strong', '?', '?']

DATE: 15/04/2023

LAB 3: CANDIDATE- ELIMINATION- ENJOY SPORT

Program 3: For a given set of training data examples stored in a .CSV file, implement and demonstrate the Candidate-Elimination algorithm to output a description of the set of all hypotheses consistent with the training examples.
Data set:Enjoysport

Example	Sky	AirTemp	Humidity	Wind	Water	Forecast	EnjoySport
1	Sunny	Warm	Normal	Strong	Warm	Same	Yes
2	Sunny	Warm	High	Strong	Warm	Same	Yes
3	Rainy	Cold	High	Strong	Warm	Change	No
4	Sunny	Warm	High	Strong	Cool	Change	Yes

ALGORITHM:

Step1: Load Data set

Step2: Initialize General Hypothesis and Specific Hypothesis.

Step3: For each training example

Step4: If example is positive example

    if attribute_value == hypothesis_value:
      Do nothing
    else:
      replace attribute value with '?' (Basically generalizing it)

Step5: If example is Negative example

    Make generalize hypothesis more specific.

? match with all the att. expected outcome as ve
∴ inconsistent.
So write all hypo. which are consistent till now.
To do that, consider one ? at a time.

CODE:

```
import numpy as np
import pandas as pd
data = pd.DataFrame(data = pd.read_csv('enjoysport.csv'))
concepts = np.array(data.iloc[:, 0:-1])
print(concepts)
target = np.array(data.iloc[:, -1])
print(target)

def learn(concepts, target):
    specific_h = concepts[0].copy()
    print("initialization of specific_h & general_h")
    print(specific_h)
    general_h = [["?" for i in range(len(specific_h))]
        for i in range(len(specific_h))]
    print(general_h)
    for i, h in enumerate(concepts):
        if target[i] == "yes":
            for x in range(len(specific_h)):
                if h[x] != specific_h[x]:
                    specific_h[x] = '?'
                    general_h[x][x] = "?"
                print(specific_h)
        print(specific_h)
        if target[i] == "no":
            for x in range(len(specific_h)):
                if h[x] != specific_h[x]:
                    general_h[x][x] = specific_h[x]
                else:
                    general_h[x][x] = '?'
        print("steps of CE Algo", i+1)
        print(specific_h)
        print(general_h)
    indices = [i for i, val in enumerate(general_h) if
val == ['?', '?', '?', '?', '?', '?']]
    for i in indices:
        general_h.remove(['?', '?', '?', '?', '?', '?'])
    return specific_h, general_h

Program 4:Write a program to demonstrate the working of the decision tree based ID3 algorithm. Use an appropriate data set for building the decision tree and apply this knowledge to classify a new sample.

Day	*Outlook*	*Temperature*	*Humidity*	*Wind*	*PlayTennis*
D1	Sunny	Hot	High	Weak	No
D2	Sunny	Hot	High	Strong	No
D3	Overcast	Hot	High	Weak	Yes
D4	Rain	Mild	High	Weak	Yes
D5	Rain	Cool	Normal	Weak	Yes
D6	Rain	Cool	Normal	Strong	No
D7	Overcast	Cool	Normal	Strong	Yes
D8	Sunny	Mild	High	Weak	No
D9	Sunny	Cool	Normal	Weak	Yes
D10	Rain	Mild	Normal	Weak	Yes
D11	Sunny	Mild	Normal	Strong	Yes
D12	Overcast	Mild	High	Strong	Yes
D13	Overcast	Hot	Normal	Weak	Yes
D14	Rain	Mild	High	Strong	No

ALGORITHM:

- Create a Root node for the tree
- If all Examples are positive, Return the single-node tree Root, with label = +
- If all Examples are negative, Return the single-node tree Root, with label = -
- If Attributes is empty, Return the single-node tree Root, with label = most common value of Target_attribute in Examples

  Otherwise Begin
- A ← the attribute from Attributes that best* classifies Examples
- The decision attribute for Root ← A
- For each possible value, v_i, of A,
- Add a new tree branch below *Root*, corresponding to the test A = v_i
- Let *Examples* $_{vi}$, be the subset of Examples that have value v_i for *A*
- If *Examples* $_{vi}$, is empty
- Then below this new branch add a leaf node with label = most common value of Target_attribute in Examples
- Else below this new branch add the subtree ID3(*Examples* $_{vi}$, Targe_tattribute, Attributes – {A}))
- End
- Return Root

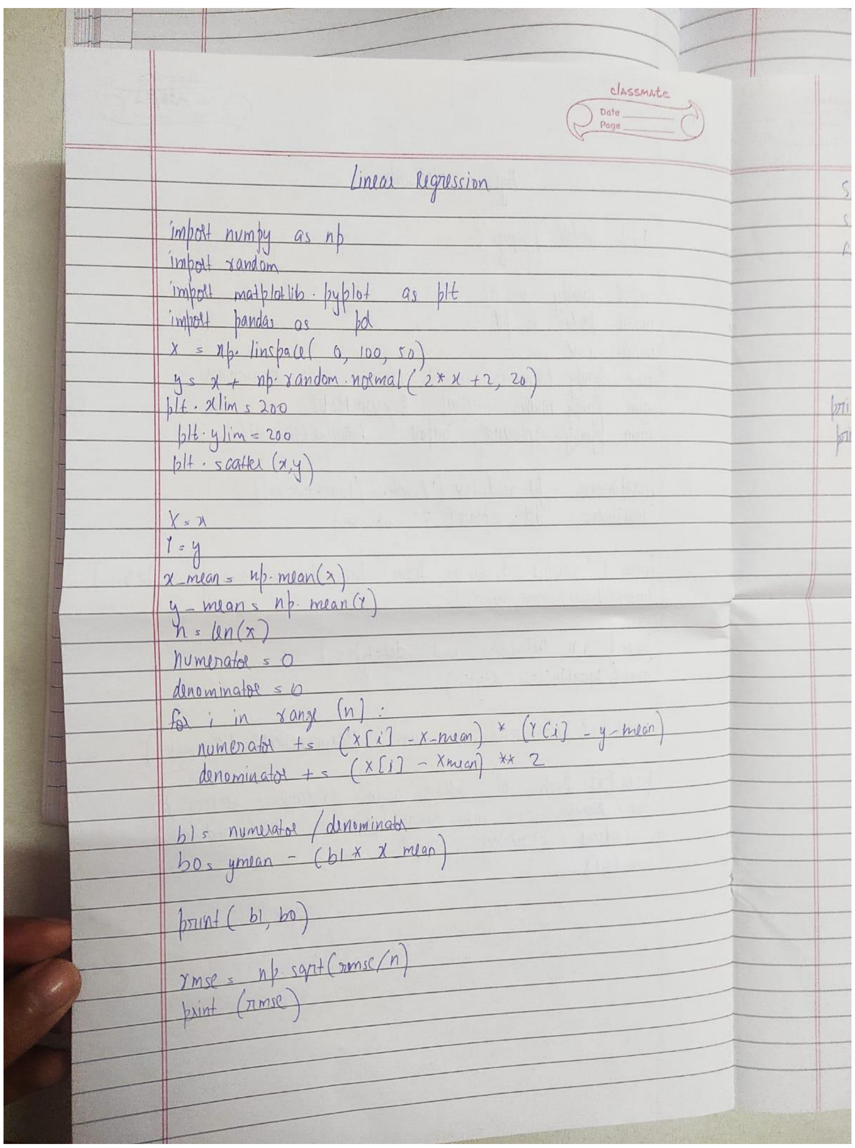
PROGRAM 5: Simple linear regression program

Dataset used:

	A	B
1	x	y
2	1	1
3	2	2
4	3	1.3
5	4	3.75
6	5	2.25
7		

ALGORITHM:

- The main function to calculate values of coefficients
- Initialize the parameters.
- Predict the value of a dependent variable by giving an independent variable.
- Calculate the error in prediction for all data points.
- Calculate partial derivatives w.r.t a0 and a1.
- Calculate the cost for each number and add them.
- Update the values of a0 and a1.



Linear Regression

```
import numpy as np
import random
import matplotlib.pyplot as plt
import pandas as pd
x = np.linspace( 0, 100, 50)
y = x + np.random.normal(2*x +2, 20)
plt.xlim = 200
plt.ylim = 200
plt.scatter (x,y)

X = x

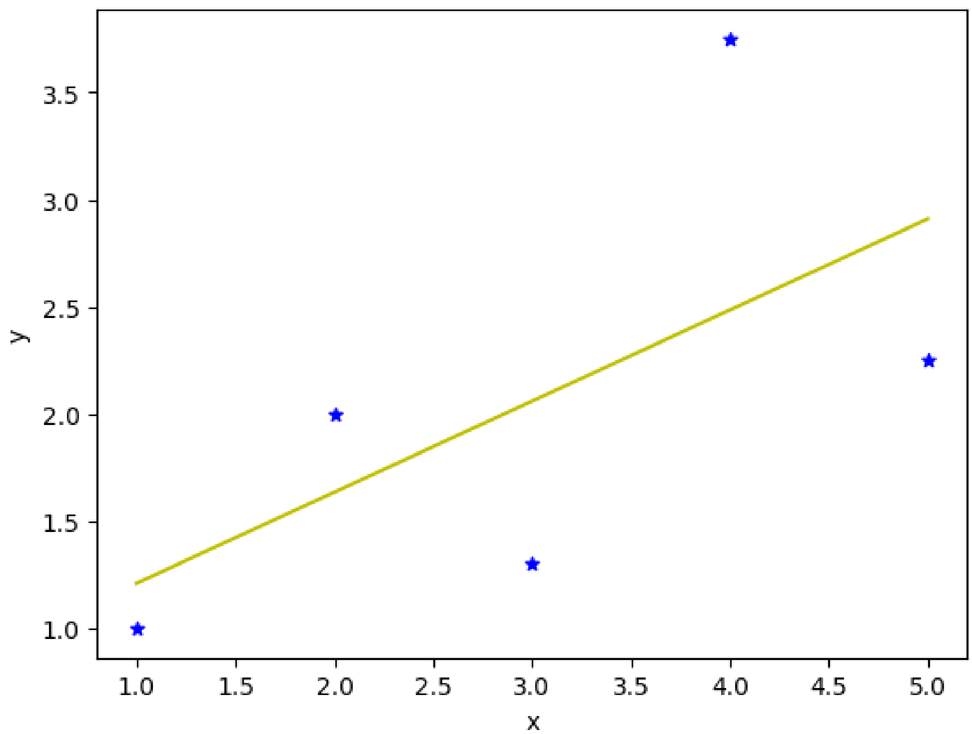
if __name__ == "__main__":
  main()
```

```
Estimated coefficients:
b_0 = 0.785000000000001
b_1 = 0.4249999999999966
```



Conclusion:

This model is not appropriate for this model. All the points of this dataset are away from the prediction line.

Program 6:Write a program to implement the naïve Bayesian classifier for a sample training data set stored as a .CSV file. Compute the accuracy of the classifier, considering few test data sets.

Data set used:

	A	B
1	outlook	play
2	rainy	Yes
3	sunny	Yes
4	overcast	Yes
5	overcast	Yes
6	sunny	No
7	rainy	Yes
8	sunny	Yes
9	overcast	Yes
10	rainy	No
11	sunny	No
12	sunny	Yes
13	rainy	No
14	overcast	Yes
15	overcast	Yes

Algorithm:

Formula for naive bayes classifier is as follows → $P(A|B)=\frac{P(B|A)P(A)}{P(B)}$

1. Convert the given dataset into frequency tables.
2. Generate Likelihood table by finding the probabilities of given features.
3. Now, use Bayes theorem to calculate the posterior probability.
4. Test accuracy of the result and visualizing the test set result.

Naive Bays Classifier

Program 7:K- means clustering

Algorithm:

Initialize k means with random values
For a given number of iterations:
 Iterate through items:
 Find the mean closest to the item by calculating the euclidean distance of the item with each of the means
 Assign item to mean
 Update mean by shifting it to the average of the items in that cluster

Dataset:

Kmeans_1BM20CS066.csv

Program 8: KNN ALGORITHM

Dataset used: Iris dataset

Algorithm:

- Select the number K of the neighbor
- Calculate the Euclidean distance of K number of neighbors
- Take the K nearest neighbors as per the calculated Euclidean distance.
- Among these k neighbors, count the number of the data points in each category.
- Assign the new data points to that category for which the number of the neighbor is maximum.

Program 9: Apply EM algorithm to cluster a set of data stored in a .CSV file. Compare the results of k-Means algorithm and EM algorithm.

Algorithm for k means clustering:

- Initialize k means with random values
- For a given number of iterations:
- Iterate through items:
- Find the mean closest to the item by calculating the euclidean distance of the item with each of the means
- Assign item to mean
- Update mean by shifting it to the average of the items in that clusters

Algorithm for EM algorithm:

- The very first step is to initialize the parameter values. Further, the system is provided with incomplete observed data with the assumption that data is obtained from a specific model.
  - This step is known as Expectation or E-Step, which is used to estimate or guess the values of the missing or incomplete data using the observed data. Further, E-step primarily updates the variables.
  - This step is known as Maximization or M-step, where we use complete data obtained from the 2^{nd} step to update the parameter values. Further, M-step primarily updates the hypothesis.
  - The last step is to check if the values of latent variables are converging or not.

Program 10: Implement the non-parametric Locally Weighted Regression algorithm in order to fit data points. Select the appropriate data set for your experiment and draw graphs.

Algorithm:

1. F is approximated near Xq using a linear function:

$$\hat{f}(x) = w_0 + \sum_{u=1}^{k} w_u K_u(d(x_u, x))$$

2. **Minimize the squared error:**

$$E_3(x_q) \equiv \frac{1}{2} \sum_{x \in k \text{ nearest nbrs of } x_q} (f(x) - \hat{f}(x))^2 \; K(d(x_q, x))$$

$$\Delta w_j = \eta \sum_{x \in k \text{ nearest nbrs of } x_q} K(d(x_q, x)) \; (f(x) - \hat{f}(x)) \; a_j(x)$$

3. It is weighted because the contribution of each training example is weighted by its distance from the query point.
